Case Study – 2

Objectives:

1. Provide the learner some more practice for exploratory data analysis.
2. Equip the learner to fit and evaluate a linear regression model.

Questions:

1. Load the data from “cereal.csv” and plot histograms of sugar and vitamin content across different cereals.

[Hint: Extract values of a specific column using their labels and use his method of pyplot]

2. The names of the manufacturers are coded using alphabets, create a new column with their full name using the below mapping.

'N': 'Nabisco',

'Q': 'Quaker Oats',

'K': 'Kelloggs',

'R': 'Raslston Purina',

'G': 'General Mills',

'P' : 'Post' ,

'A': 'American Home Foods Products

Create a bar plot where each manufacturer is on the y axis and the height of the bars depicts the number of cereals manufactured by them.

[Hint: Try using count plot this time or bar method of pyplot]

3. Extract the rating as your target variable ‘y’ and all numerical parameters as your predictors ‘x’. Separate 25% of your data as a test set.

4. Fit a linear regression module and measure the mean squared error on the test dataset.

[Hint: Explore linear models and metrics section of sklearn documentation]
